AMENDMENTS TO THE CLAIMS

1. (Currently Amended) A method for operating a constant current circuit, comprising: after connecting a sampling capacitor connected between a gate and a source of a <u>first</u> transistor and a drain of the <u>first</u> transistor to a reference current source and setting a voltage across the sampling capacitor to a voltage between the gate and the source produced while the <u>first</u> transistor is driven by a reference current of the reference current source,

cutting off the connection among the sampling capacitor, the <u>first</u> transistor and the reference current source, as well as connecting the drain of the <u>first</u> transistor to a driving target, and driving the driving target by a current of the <u>first</u> transistor due to the voltage between the gate and the source that is set in the sampling capacitor,

wherein said cutting off the connection comprises applying a first signal to a gate of a second transistor connected between the drain of the first transistor and the reference current source, and

a second signal that is opposite said first signal to a gate of a third transistor connected between the gate and drain of the first transistor.

2. (Previously Presented) The method for operating a constant current circuit according to claim 1, further comprising:

repeating a period for setting the voltage across the sampling capacitor and a period for driving the driving target.

3. (Currently Amended) A flat display device constructed so that a display section made of pixels arranged in a matrix form, a vertical driving circuit for sequentially selecting the pixels of the display section through gate lines, and a horizontal driving circuit for driving pixels selected through the gate lines, by signal lines of the display section,

characterized in that:

the horizontal driving circuit comprises:

a digital-to-analog conversion circuit for performing digital-to-analog conversion processing of gradation data indicative of gradations of the pixels; and

a buffer circuit for driving the signal lines by means of an output signal from the digital-to-analog conversion circuit;

the buffer circuit drives the signal lines by a source follower circuit formed by connecting a constant current circuit to a source of a transistor; and

the constant current circuit is configured such that, after connecting a sampling capacitor connected between a gate and a source of a <u>first</u> transistor and a drain of the <u>first</u> transistor to a reference current source and setting a voltage across the sampling capacitor to a voltage between the gate and the source produced while the <u>first</u> transistor is driven by a reference current of the reference current source, cuts off the connection among the sampling capacitor, the <u>first</u> transistor and the reference current source, as well as connects the drain of the <u>first</u> transistor to a driving target and drives the driving target by a current of the <u>first</u> transistor due to the <u>first</u> voltage between the gate and the source that is set in the sampling capacitor,

wherein said cutting off the connection comprises applying a first signal to a gate of a second transistor connected between the drain of the first transistor and the reference current source, and

a second signal that is opposite said first signal to a gate of a third transistor connected between the gate and drain of the first transistor.

- 4. (Previously Presented) The flat display device according to claim 3, wherein the constant current circuit is configured for repeating a period for setting the voltage across the sampling capacitor and a period for driving the driving target, the period for setting the voltage across the sampling capacitor being set as a period for precharge of the display section.
 - 5. (Currently Amended) A constant current circuit, comprising:
- a <u>first</u> transistor having a gate, a source, and a drain, the drain of the <u>first</u> transistor being configured for selective connection to a reference current source; [[and]]

a sampling capacitor configured for selective connection between the gate and the source of the <u>first</u> transistor, for setting a voltage across the sampling capacitor to a voltage between the gate and the source produced while the <u>first</u> transistor is driven by a reference current of the reference current source,

wherein the drain of the <u>first</u> transistor is selectively connected to a driving target after setting said voltage across the sampling capacitor, for driving the driving target by a current of the transistor due to the voltage between the gate and the source that is set in the sampling capacitor;

a first signal applied to a gate of a second transistor having a gate, a source, and a drain, connected between the drain of the first transistor and the reference current source; and

a second signal that is opposite said first signal applied to a gate of a third transistor having a gate, a source, and a drain, connected between the gate and drain of the first transistor.

6. (Previously Presented) The constant current circuit according to claim 5, wherein a period for setting the voltage across the sampling capacitor and a period for driving the driving target are repeated, the period for setting the voltage across the sampling capacitor being set as a period for pre-charge of a display section.
